

Sheet (1) Solution

1. First we calculate the time needed to transport the data:

Time = distance / speed

$$= 5000 \text{ km} / 1000 \text{ km/h} = 5 \text{ hrs.}$$

Each floppy weighs 30 gm, and load capacity of airplane is $10^4 \text{ kg} = 10^7 \text{ gms.}$

Hence, number of floppies carried = $10^7 \text{ gms} / 30 \text{ gms} = 333333$

Each floppy contains 1.44 Mbytes = $1.44 \times 2^{20} \times 8 \text{ bits} = 12.079 \times 10^6 \text{ bits}$

So, 333333 floppies will contain:

$$12.079 \times 10^6 \times 333333 \text{ bits} = 4026329 \times 10^6 \text{ bits}$$

Now data transmission speed = data carried in bits / time

$$= 4026329 \times 10^6 \text{ bits} / (5 \text{ hrs} \times 60 \text{ mins} \times 60 \text{ secs})$$

$$= 223.68 \times 10^6 \text{ bits/sec}$$

$$= 223.68 \text{ Mbps.}$$

2. No. of devices = 5.

No. of guard bands required between them is 4.

Hence total bandwidth = $(4000 \times 5) + (200 \times 4) = 20.8 \text{ KHz.}$

3. Telephone link loss = 20 dB, Input signal power = 0.9 watt ,Output noise power = 10 uwatt .

$$\text{a) Output SNR(dB)} = 10 \times \log_{10} (\text{Output signal power/output noise power})$$

Since

$$\text{Line loss (dB)} = 10 \times \log (\text{Input signal power/Output signal power}) = 20 \text{ dB}$$

It follows

$$\text{Input signal power/Output signal power} = 10^2$$

$$\& \text{ Output signal power} = 0.9 \text{ watt} / 10^2 = 9 \text{ mwatt}$$

$$\text{Hence, Output SNR (dB)} = 10 \times \log ((9 \times 10^{-3}) / (10 \times 10^{-6})) = 29.54 \text{ dB}$$

b) Capacity of phone line is computed from:

$$\text{Capacity} = B \cdot \log_2(1 + \text{SNR})$$

where: $B = 2500 \text{ KHz}$

$$\text{SNR}(\text{ratio}) = 9 \text{ mwatt} / 10 \text{ uwatt} = 900$$

Hence, $\text{Capacity} = 2500 \cdot 10^3 \cdot \log_2(1 + 900) = 24.538 \text{ Mbit/sec}$

c) Length of phone line is computed as follows:

Phone line attenuation rate = 6 dB/Km

Input signal power = 0.9 watt

Minimum output signal power = 0.005 watt

Hence,

$$\begin{aligned} \text{Max allowable line attenuation} &= 10 \cdot \log(\text{input signal} / \text{output signal}) \\ &= 10 \cdot \log(0.9 / 0.005) = 22.55 \text{ dB} \end{aligned}$$

$$\begin{aligned} \text{Max allowable line length} &\leq (\text{Max attenuation} / \text{attenuation rate}) \\ &\leq 22.55 / 6 = 3.758 \text{ Km} \end{aligned}$$

4. Analog broadcast television channel has bandwidth (B) = 10 MHz

a) For (64-QAM) signal with Symbol rate = $8 \cdot 10^6 \text{ QAM symbol/sec}$

$$\begin{aligned} \text{Bit rate} &= \text{Symbol rate} \cdot \log_2 M \quad (M = \text{number of symbols} = 64) \\ &= 8 \cdot 10^6 \cdot \log_2(64) = 48 \text{ Mbit/sec} \end{aligned}$$

b) To get minimum channel SNR, we use Shannon's law :

$$\text{Bit rate} = B \cdot \log_2(1 + \text{SNR})$$

$$48 \cdot 10^6 = 10 \cdot 10^6 \cdot \log_2(1 + \text{SNR})$$

Hence, $\text{SNR} = 26.857$

c) If bandwidth is doubled ($B_2 = 2 \cdot B_1$)

To have same the bit rate

$$B_1 \cdot \log_2(1 + \text{SNR}_1) = B_2 \cdot \log_2(1 + \text{SNR}_2)$$

$$(\frac{1}{2}) \cdot \log_2(1 + \text{SNR}_1) = \log_2(1 + \text{SNR}_2)$$

$$\log_2(1 + \text{SNR}_1)^{\frac{1}{2}} = \log_2(1 + \text{SNR}_2)$$

$$(1 + \text{SNR}_2) = (1 + \text{SNR}_1)^{\frac{1}{2}}$$

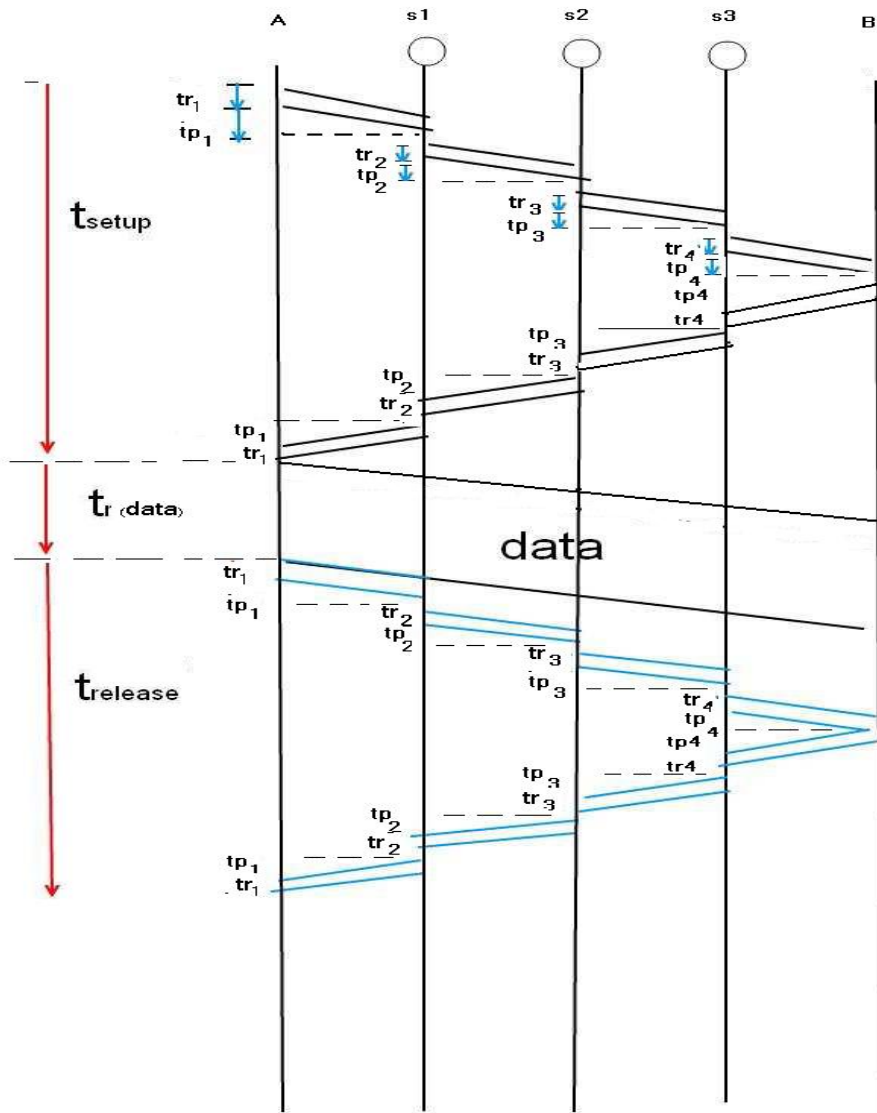

$$\text{SNR}_1 = 26.8576 \rightarrow \text{SNR}_2 = 4.278$$

$$\frac{\text{SNR}_2}{\text{SNR}_1} = \frac{\text{Signal}_2 \cdot \text{Noise}_1}{\text{Signal}_1 \cdot \text{Noise}_2} \quad \& \quad \frac{\text{Noise}_1}{\text{Noise}_2} = \frac{B_1}{B_2} = \frac{1}{2}$$

$$\frac{\text{Signal}_2}{\text{Signal}_1} = \frac{2 \cdot 4.278}{26.8576} = 0.318$$

5. File to be transmitted along path between source and destination over 3 switches

The time to deliver the file consists of the time it takes to establish the circuit (1 sec), the propagation delay ($t_p=2$ ms), the time it takes to transmit the file over the link ($= K/4 \times 10^6$), and time of circuit release ($=1$ sec) (Take it as circuit setup if not given)

$$t_{r1} = t_{r2} = t_{r3} = t_{r4} = t_r; t_{p1} = t_{p2} = t_{p3} = t_{p4} = t_p = 2\text{ms}$$

$$\text{Total Delay} = t_{\text{setup}} + t_{\text{r(Data)}} + t_{\text{release}}$$

$$\text{Total Delay} = 1 + \frac{K}{4 \times 10^6} + 1 = \left(2 + \frac{K}{4 \times 10^6}\right) \text{sec}$$

- a) Packet Switching with acknowledgment with packet size = 1Kbits = 1000bits (payload) + 24bits(header)

Since, number of packets = $\frac{K}{1000}$

Then time needed to transfer this file = number of packets * [time to transfer one packet + time of receiving packet acknowledge]

$$\begin{aligned}
 \text{Time to transfer one packet} &= 4 * t_p + 4 * t_r \\
 &= 4 * 2\text{ms} + 4 * 1024 / (4 * 10^6) \\
 &= 9.042 \text{ ms}
 \end{aligned}$$

$$\text{Time needed to transfer this file} = \frac{K}{1000} * [9.042 + 10] \text{ msec}$$

$$= 19.042 * 10^{-6} K \text{ sec}$$

b) Packet Switching without acknowledgment with packet size = 1Kbits = 1000 bits (payload) + 24bits (header)

Time needed to transfer this file = time to transfer last packet + transmission time of remaining packets

Time to transfer first packet is (as before) = 9.042 ms

Transmission time of remaining packets = $\left[\frac{K}{1000} - 1\right] * tr_1$

Time needed to transfer this file = $9.042 + 0.256 * \left[\frac{K}{1000} - 1\right] \text{ ms}$

For scenario (a) to be faster than scenario (c), we should have:

Delay of scenario (a) < Delay of scenario (c)

$$\left(2 + \frac{K}{4 * 10^6}\right) < 9.042 * 10^{-3} + 0.256 * \left[\frac{K}{1000} - 1\right] * 10^{-3}$$

or $0.256 * 10^{-6} * K - 0.25 * 10^{-6} * K > 2 - 9.042 * 10^{-3} + 0.256 * 10^{-3}$

$$K > 331.7836 * 10^6 \text{ bits}$$

c) Virtual-circuit packet-switching

$$t_{r'1}=t_{r'2}=t_{r'3}=t_{r'4}, \quad t_{p1}=t_{p2}=t_{p3}=t_{p4}$$

$$\begin{aligned} \text{Time needed to deliver the file} &= t_{\text{setup}} + t_r (\text{of all data packets}) + t_{\text{release}} \\ &= 1 + 0.256 \times 10^{-3} \times \left[\frac{K}{1000} \right] + 1 = 2 + 0.256 \times 10^{-3} \times \left[\frac{K}{1000} \right] \text{sec} \end{aligned}$$

d) message switching

$$tr1=tr2=tr3=tr4=tr; tp1=tp2=tp3=tp4=tp$$

Time needed to deliver file

= propagation time on the four links + transmission time at source +
transmission time at three intermediate nodes

$$= 4 * t_p + 4 * t_{r(message)} = 4 * 2ms + 4 * K / (4 * 10^6)$$

$$= (8 + 10^{-3} K) ms$$

f)

The maximum time elapses if the bit falls at the beginning of a new packet. We must first wait for the entire packet to be generated, for the packet to be transmitted over the 4 Mbps link, and for propagation delay on four links:

$$\text{Time delay} = \text{Packetization time} + \text{Time to transfer one packet} \\ = \frac{45 \times 8}{64 \times 1000} + 4 \times t_r + 4 \times t_p = \frac{45 \times 8}{64 \times 1000} + 4 \times \frac{48 \times 8}{4 \times 10^6} + 4 \times 2 \times 10^{-3} = 0.014009 \text{ sec}$$

One may suggest that Host B reproduces the first bit as soon as the first bit of the first packet arrives (without waiting for the entire packet to arrive). In practice, it is more logical to wait for the full packet to arrive (to be able to check it for errors, among other things) then decode it again.

6. (For your answer to be complete, you should draw time sequence diagrams before writing down the mathematical expressions)

- a) With Circuit switching: $t_r = 3000 \times 8 / 5 \times 10^6 = 4.8 \text{ ms}$

Hence, total time = setup time + t_r + release time

$$= 1 + 4.8 \times 10^{-3} + 1 = 2004.8 \text{ ms} \quad (t_{\text{setup}} = t_{\text{release}} = 1 \text{ sec, not 1 ms})$$

- b) With Packet switching, 2 intermediate points, Packet size = 1 KB

Header = 24 B, without waiting acknowledgment

Total time = time to transfer first packet + transmission time of remaining packets

$$t_p = \frac{100 \times 10^3}{30 \times 10^6} = 3.33 \text{ ms}$$

$$\text{Number of packets} = \frac{3000}{2^{10} - 24} = 3$$

$$\text{Time to transfer 1st packet} = 3 \times t_p + 3 \times t_r = 3 \times \frac{100 \times 10^3}{30 \times 10^6} + 3 \times 4.8 = 24.40 \text{ ms}$$

$$\text{Transmission Time of remaining packets} = (3-1) \times 4.8 \times 10^{-3} = 9.6 \text{ ms}$$

$$\text{Total time} = 24.4 + 9.6 = 34.0 \text{ ms}$$

- c) For Packet switching, with acknowledgment

Time needed to transfer file = Number of packets * [time to transfer one packet + time of receiving packet acknowledge]

$$= 3 \times [24.40 \text{ ms} + 3 \times \frac{100 \times 10^3}{30 \times 10^6} \text{ ms}] = 0.1032 \text{ sec}$$

(Assume time of receiving packet acknowledge = $3 \times \frac{100 \times 10^3}{30 \times 10^6} \text{ ms}$)

- d) With Packet switching serving 30 users

$$\text{Probability that 5 users are active} = {}^{30}C_5 \times (.4)^5 \times (.6)^{25} = 0.0041$$
