## 2 System Performance Evaluation

### 2.1 Definitions

System: a collection of components which are organized and interact in order to fulfill a common task

Performance: The degree to which a system or component accomplishes its designated functions within given constraints, such as speed, accuracy, or memory usage.

### 2.2 Performance Evaluation Approaches

- Measurements
- System unavailable during design phase
- Discrete Event Simulation (DES)
- Time consuming task for accurate results.
- Analysis
- Oversimplified assumptions
* Is the model logically correct, complete, or overly detailed?
* Are the distributional assumptions justified?
* How sensitive are the results to simplifications in the distributional assumptions?
* Are other stochastic properties, such as independence assumptions, valid?
* Is the model represented on the appropriate level?

## 3 Probability Basics revived :)

### 3.1 Probability Models

- Sample Space: is the set of all possible outcomes of an experiment or random trial. It is often denoted $\mathrm{S}, \Omega$, or U (for "universe")
- Event: subset of the sample space
- Algebra of Events. Revise any probability book
- Probability Axioms

$$
\begin{aligned}
& \text { (A1): For any event } A, 1>P(A) \geq 0 \\
& (A 2): P(S)=1 \\
& (A 3): P(A \cup B)=P(A)+P(B)(\text { if } A \cap B=\emptyset)
\end{aligned}
$$

Conditional Probability $\mathrm{P}(\mathrm{A} \mid \mathrm{B})$ : prob. that A occurs, given that ' B ' has occurred

$$
P(A \mid B)=\frac{P(A \cap B)}{P(B)}, \quad P(B) \neq 0
$$

A and B are said to be mutually independent, iff,

$$
P(A \mid B)=P(A)
$$

Hence

$$
\begin{aligned}
P(A \cap B) & =P(A) P(B \mid A) \\
& =P(A) P(B)
\end{aligned}
$$

- Independence Vs. Mutually Exclusive
- the probability of the union of mutually exclusive events is the sum of their probabilities
- the probability of the intersection of two mutually independent events is the product of their probabilities

### 3.2 Discrete Random Variables

- A random variable (RV) X is a mapping (function) from the sample space $S$ to the set of real numbers

$$
X: S \rightarrow R: \text { that is, } X(s) \in \Re \quad \forall s \in S .
$$

- If image(X ) finite or countable infinite, X is a Discrete RV
- $A_{x}$ : set of all sample points such that,

$$
\begin{gathered}
\{s \mid X(s)=x\} \\
P\left(A_{x}\right)=P(X=x)=P(s \mid X(s)=x)=\sum_{X(s)=x} P(s)
\end{gathered}
$$

- Probability Mass Function (PMF)

$$
p_{X}(x)=P(X=x)=\sum_{X(s)=x} P(s)
$$

- PMF Properties

$$
\begin{gathered}
0 \leq p_{X}(x) \leq 1 \quad \forall x \in R \\
\sum_{x \in R} p_{X}(x)=1
\end{gathered}
$$

- Cumulative Distribution Function (CDF)

$$
\begin{aligned}
F_{X}(t) & =P(-\infty<X \leq t)=P(X \leq t) \\
& =\sum_{x \leq t} p_{X}(x)
\end{aligned}
$$

- CDF Properties

$$
\begin{aligned}
& P(a<X \leq b)=P(X \leq b)-P(X \leq a)=F(b)-F(a) \\
& 0 \leq F(x) \leq 1 \text { for }-\infty<x<\infty \\
& F(x) \text { is monotone in } x \text { and } x_{1} \leq x_{2} \text {, then } \\
& P\left(-\infty<X \leq x_{1}\right) \leq P\left(-\infty<X \leq x_{2}\right) \\
& \lim _{x \rightarrow-\infty} F(x)=0 \text { and } \lim _{x \rightarrow \infty} F(x)=1 \\
& \text { If } x_{i+1}>x_{i} \text {, then, } F\left(x_{i+1}\right)=F\left(x_{i}\right)+p_{X}\left(x_{i+1}\right)
\end{aligned}
$$

### 3.3 Common Discrete RV

### 3.3.1 Constant Random Variable

- PMF

$$
p_{X}(x)= \begin{cases}1 & \text { if } x=c \\ 0 & \text { otherwise }\end{cases}
$$

- CDF

$$
F_{X}(t)= \begin{cases}0 & \text { if } x<c \\ 1 & \text { otherwise }\end{cases}
$$

### 3.3.2 Discrete Uniform RV

- Discrete RV X that assumes $n$ discrete value with equal probability $1 / n$
- Discrete uniform pmf

$$
p_{X}\left(x_{i}\right)= \begin{cases}\frac{1}{n}, & \text { if } x_{i} \in \text { image of } X \\ 0 & \text { otherwise }\end{cases}
$$

- Discrete uniform distribution function

X can take integer values $1,2, \ldots ., \mathrm{n}$, then

$$
F(x)=\sum_{i=1} p_{X}(i)=\frac{\lfloor x\rfloor}{n}
$$

### 3.3.3 Bernoulli RV

- generated by experiments that has a binary valued outcome, e.g. $\{0,1\}$, $\{$ Success, Failure $\}$
- The experiment is named Bernoulli trial (BT) and the generated RV is called Bernoulli RV
- PMF
$-\mathrm{P}(\mathrm{X}=1)=\mathrm{p}$
$-\mathrm{P}(\mathrm{X}=0)=(1-\mathrm{p})$
- CDF

$$
-F(x)=\left\{\begin{array}{cc} 
& 0 \\
q & 0 \leq x<1 \\
& 1 \quad x>1
\end{array}\right.
$$

### 3.3.4 Binomial Random Variable

- Generated from n Bernoulli trials.
- RV $Y_{n}$ : no. of successes in $n$ BTs
- PMF b(k;n,p)

$$
\begin{aligned}
p_{k} & =P\left(Y_{n}=k\right)=p_{Y_{n}}(k) \\
& = \begin{cases}\binom{n}{k} p^{k}(1-p)^{n-k}, & 0 \leq k \leq n \\
0 & \text { otherwise }\end{cases}
\end{aligned}
$$

- CDF

$$
B(t ; n, p)=F_{Y_{n}}(t)=\sum_{i=0}^{\lfloor t\rfloor}\binom{n}{i} p^{i}(1-p)^{n-i}
$$

Example: Packet Transmission

- The bit is transmitted successfully with prob $p$
- The probability of no error transmission for a packet containing N bits is

$$
P_{\text {errorFree }}=p^{n}
$$

- The probability of recovering packets with at most $m$ erroneous bits using forward error correction (FEC) is

$$
P_{\text {recovery }}=\sum_{i=0}^{m}\binom{n}{m} p^{n-m}(1-p)^{m}
$$

### 3.3.5 Geometric RV

- Number of independent trials upto and including the 1st success.

Define RV $Z(\in S)$ : sample point $0^{i-1} 1=i$
$p_{Z}(i)=q^{i-1} p=p(1-p)^{i-1}, i=1,2,3, \ldots$
$F_{Z}(t)=\sum_{i=1}^{\lfloor t\rfloor} p(1-p)^{i-1}=1-(1-p)^{\lfloor t\rfloor}, t \geq 0$

- Geometric RV is the only discrete distribution that exhibits MEMORYLESS property.
- given that the first success has not yet occurred, the conditional probability distribution of the number of additional trials does not depend on how many failures have been observed.

$$
\begin{aligned}
P(Y= & i \mid Z>n)=\frac{P(Z=n+i, Z>n)}{P(Z>n)} \\
& =p q^{i-1}=p_{Z}(i)
\end{aligned}
$$

- Example: number or loops until exiting
- Number of failures until the first success $\rightarrow$ modified geometric distribution

### 3.3.6 Poisson RV

- RV such as "no. of arrivals in an interval $(0, t)$ "

$$
f(k, \lambda t)=\frac{\mathrm{e}^{-\lambda t}(\lambda t)^{k}}{k!}, k=0,1,2, \ldots
$$

- The Poisson distribution can be derived as a limiting case to the binomial distribution as the number of trials goes to infinity and the expected number of successes remains fixed.
- Poisson RV can be used as an approximation of the binomial distribution if n is sufficiently large and p is sufficiently small.
- There is a rule of thumb stating that the Poisson distribution is a good approximation of the binomial distribution if n is at least 20 and p is smaller than or equal to 0.05 , and an excellent approximation if $\mathrm{n} \geq 100$ and $\mathrm{np} \leq 10$
- In a small interval, $\Delta t$, prob. of new arrival $=\lambda \Delta t$.
- $\operatorname{pmf} \mathrm{b}(\mathrm{k} ; \mathrm{n}, \lambda \mathrm{t} / \mathrm{n})$ [Binomial]

$$
b\left(k ; n, \frac{\lambda t}{n}\right)=\binom{n}{k}\left(\frac{\lambda t}{n}\right)^{k}\left(1-\frac{\lambda t}{n}\right)^{n-k}, k=0,1, \ldots, n
$$

- $\operatorname{CDF~} \mathrm{B}(\mathrm{k} ; \mathrm{n}, \lambda \mathrm{t} / \mathrm{n})=\sum_{k} b\left(k ; n ; \frac{\lambda t}{n}\right)$

$$
n \xrightarrow{\lim } \infty \frac{n!}{(n-k)!k!}\left(\frac{\lambda t}{n}\right)^{k}\left(1-\frac{\lambda t}{n}\right)^{n-k} \lim _{h \rightarrow 0}(1+h)^{h}=e
$$

## Poisson Process

- Poisson process is a stochastic process which counts the number of events and the time that these events occur in a given time interval.
- The number of arrivals in the given time interval is a Poisson RV.
- The time between each pair of consecutive events has an exponential distribution with parameter $\lambda$. (prove)
- Sum of two Poisson RV is a new Poisson RV.
- Poisson process is used as a typical arrival process (call arrival, Requests for individual documents on a web server, packet arrival, ....)

### 3.4 Probability Generating Function (PGF)

- Letting, $\mathrm{P}(\mathrm{X}=\mathrm{k})=\mathrm{pk}$, PGF of X is defined by

$$
G_{X}(z)=\sum_{k=0}^{\infty} p_{k} z^{k}=p_{0}+p_{1} z^{1}+p_{2} z^{2}+\ldots+p_{k} z^{k}+\ldots
$$

- Can be used to estimate the moments of any RV.
- Theorem 1: If two RVs have the same PGF, then they have the same distribution ( One-to-one mapping: pmf (or CDF) $\Leftrightarrow \mathrm{PGF}$ )
- Theorem 2: The PGF of a sum of RVs is the product of their individual PGFs

Example: proving the sum of two independent Poisson RV is another Poisson RV
Proof:
the PGF od Poisson Random Variable can be expressed as
$G_{X}(z)=\sum_{k=0}^{\infty} p_{k} z^{k}=\sum_{k=0}^{\infty} \frac{e^{-\lambda t}(\lambda t)^{k}}{k!} z^{k}=e^{-\lambda t}\left[e^{\lambda t z}\right]=e^{\lambda t(z-1)}$
Since the PGF of the sum of two random variables ( X and Y ) is the product of their individual PGFs
then the PGF of the sum (M) can be expressed as
$G_{M}(z)=G_{X} * G_{Y}=e^{\lambda t(z-1)} * e^{\eta t(z-1)}=e^{(\lambda+\eta) t(z-1)}$
Note that $G_{M}(z)$ has the same form of Poisson RV PGF. Then M is a Poisson RV with parameter $(\lambda+\eta)$

### 3.5 Maximum of two RVs

Let $\mathrm{Z}=\max \{\mathrm{X}, \mathrm{Y}\}$

$$
\begin{aligned}
P_{Z}(z) & =P(\max [X, Y]<z) \\
& =P(X<z, Y<z) \\
& =\underbrace{P(X<z) P(Y<z)}_{\text {by independence }}
\end{aligned}
$$

- The CDF of the maximum is the product of the CDF of involved independent Rvs
- Determine the distribution of the minimum of two RVs.

### 3.6 Homework

- Prove that geometric distribution is memoryless.
- Derive the PGF of discussed Rvs
- Show that Sum of two Binomial RVs is another Binomial distribution.
- Show that the min of two geometric RV is another geometric RV.
